- Wave Properties and Calculations
- Sound Wave Behavior and Characteristics
- Wave Interference and Standing Waves
- Doppler Effect
- Resonance and Applications

Detailed Answers to Conceptual Physics Exercises in Chapter 24

Below, we explore typical exercises with detailed, step-by-step answers to help you understand the concepts thoroughly.

1. Wave Properties and Calculations

Exercise 1: A wave on a string has a frequency of 10 Hz and a wavelength of 2 meters. What is the speed of the wave?

Answer:

Using the wave speed formula:

$$v = f \times \lambda$$

Where:

- v = wave speed
- f = frequency = 10 Hz
- λ = wavelength = 2 m

Calculation:

$$v = 10 \, \text{Hz} \times 2 \, \text{m} = 20 \, \text{m/s}$$

Therefore, the wave speed is 20 meters per second.

Exercise 2: If a sound wave travels at 340 m/s in air and has a wavelength of 0.68 meters, what is its frequency?

Answer:

Using the same wave equation:

$$f = \frac{v}{\lambda}$$

Calculation:

$$f = \frac{340 \, \text{m/s}}{0.68 \, \text{m}} \approx 500 \, \text{Hz}$$

The frequency of the sound wave is approximately 500 Hz.

2. Sound Wave Behavior and Characteristics

Exercise 3: Explain why sound travels faster in water than in air.

Answer:

Sound travels faster in water than in air primarily because water molecules are more tightly packed

and interact more strongly than air molecules. The increased density and elastic properties of water allow sound waves to propagate more quickly. Specifically:

- Density: Water is denser, providing a medium that transmits vibrations more efficiently.
- Elasticity: Water's elastic properties are higher, meaning it can restore its shape after deformation more effectively.

As a result, the speed of sound in water (~1482 m/s) exceeds that in air (~343 m/s at room temperature).

Exercise 4: Describe how the amplitude of a sound wave affects its loudness.

Answer:

The amplitude of a sound wave correlates directly with its loudness. Larger amplitudes mean greater energy in the wave, resulting in louder sounds that are perceived as more intense. Conversely, smaller amplitudes produce softer sounds. This relationship is subjective but generally accepted: as amplitude increases, loudness increases proportionally to the square root of the energy.

3. Wave Interference and Standing Waves

Exercise 5: What is the difference between constructive and destructive interference?

Answer:

- Constructive interference occurs when two waves meet in phase, meaning their crests and troughs align. The result is a wave with greater amplitude, leading to a louder or more intense wave.
- Destructive interference occurs when two waves meet out of phase, with crests aligning with troughs. This causes the waves to cancel each other out partially or completely, resulting in reduced amplitude or silence.

In summary:

- Constructive interference amplifies wave effects.
- Destructive interference diminishes or cancels wave effects.

Exercise 6: In a string fixed at both ends, standing waves form at specific frequencies. What determines these frequencies?

Answer:

Standing wave frequencies are determined by the length of the string, the wave speed, and the boundary conditions. The fundamental frequency (first harmonic) occurs when the string vibrates with a single antinode in the middle, and higher harmonics are integer multiples of this frequency.

The formula for the n th harmonic:

$$f_n = n \times \frac{v}{2L}$$

Where:

- n = harmonic number (1, 2, 3, ...)
- v = wave speed in the string
- L = length of the string

Thus, the specific frequencies at which standing waves form are quantized and depend on these parameters.

4. Doppler Effect

Exercise 7: A police siren emits a sound at a frequency of 1000 Hz. If the police car approaches an observer at 30 m/s and the speed of sound is 340 m/s, what frequency does the observer perceive?

Answer:

Using the Doppler effect formula for a moving source approaching a stationary observer:

$$f' = f \times \frac{v + v_o}{v}$$

Where:

- f' = perceived frequency
- f = emitted frequency = 1000 Hz
- v = speed of sound = 340 m/s
- v_o = velocity of source toward the observer = 30 m/s

Calculation:

$$[f' = 1000 \, \text{Hz} \times \frac{340 \, \text{m/s} + 30 \, \text{m/s}}{340 \, \text{m/s}} = 1000 \, \text{Hz} \times \frac{370}{340} \approx 1000 \times 1.088 = 1088 \, \text{Hz}]$$

The observer perceives the sound at approximately 1088 Hz.

Exercise 8: If the same source moves away from the observer at 30 m/s, what is the perceived frequency?

Answer:

For a source moving away:

$$[f' = f \times \frac{v}{v + v_o}]$$

Calculation:

$$[f' = 1000 \, \text{Hz} \times \frac{340}{340 + 30} = 1000 \times \frac{340}{370} \approx 1000 \times 0.919 = 919 \, \text{Hz}]$$

The observer perceives the sound at approximately 919 Hz.

5. Resonance and Applications

Exercise 9: Describe how resonance can cause a glass to break when exposed to a certain sound frequency.

Answer:

Resonance occurs when an external sound wave matches the natural frequency of an object, causing it to vibrate with increasing amplitude. If the sound's amplitude is sufficiently high and the frequency precisely matches the object's natural frequency, the vibrations can become intense enough to weaken or break the object.

In the case of a glass:

- When exposed to a sound at its natural frequency, the glass vibrates vigorously.
- These vibrations can exceed the material's structural limits.
- The resulting stress causes the glass to shatter.

This principle is exploited in musical performances and demonstrates the importance of matching

frequencies in resonance phenomena.

Exercise 10: How do engineers utilize standing waves and resonance in designing musical instruments?

Answer:

Engineers and instrument makers exploit resonance and standing waves to produce specific notes:

- String instruments: Strings are tuned so that their length and tension produce standing waves at desired frequencies.
- Wind instruments: The length of air columns is adjusted to resonate at particular frequencies, producing specific pitches.
- Resonance chambers: These amplify sound by creating standing waves, enhancing volume and tonal quality.

By controlling these parameters, designers craft instruments that produce clear, stable notes with desired tonal characteristics.

- Clarifies misconceptions through detailed explanations.

Common Types of Exercises and Their Solutions

Chapter 24 exercises typically include conceptual questions, quantitative problems involving calculations, and real-world application scenarios. Below, we explore representative examples with detailed solutions.

1. Understanding Electromagnetic Induction

Question:

What causes an emf to be induced in a coil of wire? Describe the process in terms of magnetic flux.

Answer:

An emf is induced in a coil of wire when there is a change in the magnetic flux passing through it. Magnetic flux (Φ) is defined as:

[

$$\Phi = B \times A \times \cos \theta$$

]

where:

- B is the magnetic field strength,
- A is the area of the coil,
- θ is the angle between the magnetic field and the normal to the coil.

Process:

- When the magnetic field (B) varies over time (either by changing the field strength, moving the coil, or changing the orientation), the magnetic flux (Φ) also changes.
- According to Faraday's Law:

[

$$\text{Induced emf } (\varepsilon) = - \frac{d\Phi}{dt}$$

]

- The negative sign indicates Lenz's law, meaning the induced emf opposes the change in flux.

Key Point:

Any change in magnetic flux—whether through movement of the coil, variation in B , or rotation—induces an emf, leading to a current if the circuit is closed.

2. Applying Faraday's Law

Question:

A coil with an area of 0.5 m^2 experiences a change in magnetic flux from 0.3 Wb to 0.1 Wb in 0.2 seconds. What is the magnitude of the induced emf?

Answer:

Given data:

- Initial flux, $(\Phi_i = 0.3, \text{Wb})$
- Final flux, $(\Phi_f = 0.1, \text{Wb})$
- Time interval, $(\Delta t = 0.2, \text{s})$

Calculate change in flux:

[

$$\Delta \Phi = \Phi_f - \Phi_i = 0.1 - 0.3 = -0.2, \text{Wb}$$

]

Using Faraday's Law:

[

$$\epsilon = - \frac{\Delta \Phi}{\Delta t} = - \frac{-0.2}{0.2} = 1, \text{V}$$

]

Interpretation:

The magnitude of the induced emf is 1 volt . The negative sign in the calculation aligns with Lenz's law, indicating the induced current opposes the change in flux.

3. Magnetic Force on a Moving Charge

Question:

Calculate the magnetic force on a proton moving at $(3 \times 10^6, \text{m/s})$ perpendicular to a magnetic field of 0.5 T .

Answer:

The magnetic force on a moving charge is given by:

$$F = q v B \sin \theta$$

where:

- $(q = 1.6 \times 10^{-19}, \text{C})$ (charge of proton),
- $(v = 3 \times 10^6, \text{m/s})$,
- $(B = 0.5, \text{T})$,
- $(\theta = 90^\circ)$ (perpendicular motion), so $(\sin \theta = 1)$.

Calculating:

$$F = (1.6 \times 10^{-19}) \times (3 \times 10^6) \times 0.5 = 2.4 \times 10^{-13}, \text{N}$$

Conclusion:

The magnetic force acting on the proton is (2.4×10^{-13}) Newtons, directed perpendicular to both the velocity and magnetic field.

4. Transformers and Energy Transfer

Question:

In a transformer with 200 turns in the primary coil and 50 turns in the secondary coil, if the primary voltage is 120 V, what is the secondary voltage?

Answer:

Transformers operate on the principle:

$$\frac{V_s}{V_p} = \frac{N_s}{N_p}$$

]

where:

- $(V_p = 120 \text{ V})$,
- $(N_p = 200)$,
- $(N_s = 50)$,
- $(V_s = ?)$

Calculating:

[

$$V_s = V_p \times \frac{N_s}{N_p} = 120 \times \frac{50}{200} = 120 \times 0.25 = 30 \text{ V}$$

]

Understanding:

This is a step-down transformer reducing voltage from 120 V to 30 V. The current in the secondary increases proportionally, assuming ideal conditions.

Physics classroom wave basics answer key

Physics Classroom Wave Basics Answer Key

Understanding the fundamental concepts of waves is essential for mastering physics, as waves are pervasive in nature and technology. The "Physics Classroom Wave Basics Answer Key" serves as a valuable resource for students and educators to verify their understanding of wave phenomena, including types of waves, properties, behaviors, and mathematical descriptions. This article provides an in-depth exploration of wave basics, offering clear explanations, key concepts, and sample questions with detailed answer keys to reinforce learning and comprehension.

Introduction to Waves

What Is a Wave?

A wave is a disturbance or oscillation that travels through space and matter, transferring energy from one point to another without the transfer of matter itself. Waves can be mechanical, requiring a medium to propagate, or electromagnetic, capable of traveling through a vacuum.

Types of Waves

Waves are broadly classified into two main categories:

- **Mechanical Waves:** These require a medium (solid, liquid, or gas) to travel through. Examples include sound waves, water waves, and seismic waves.
- **Electromagnetic Waves:** These do not require a medium and can travel through the vacuum of space. Examples include light, radio waves, X-rays, and microwaves.

Wave Properties and Characteristics

Key Properties of Waves

Understanding wave properties is fundamental to analyzing wave behavior. The main properties include:

- **Wavelength (λ):** The distance between two consecutive points in phase on a wave (e.g., crest to crest or trough to trough). It is measured in meters (m).
- **Frequency (f):** The number of wave cycles that pass a fixed point per second. It is measured in hertz (Hz).
- **Period (T):** The time it takes for one complete wave cycle to pass a point. It is the reciprocal of frequency ($T = 1/f$).
- **Wave Speed (v):** The speed at which the wave propagates through the medium. It is related to wavelength and frequency by the equation $v = \lambda f$.
- **Amplitude (A):** The maximum displacement of points on the wave from the rest position, related to wave energy.
- **Wavefront:** The locus of points that vibrate in phase, representing the crest or trough at a particular instant.

Wave Equation

The fundamental relationship connecting wave speed, wavelength, and frequency is given by:

$$v = \lambda f$$

This equation is crucial for solving many wave-related problems and understanding how waves behave in different media.

Types of Mechanical Waves

Transverse Waves

In transverse waves, the particle displacement is perpendicular to the direction of wave propagation. Examples include waves on a string and water waves.

- The crest is the highest point of the wave.
- The trough is the lowest point.

Longitudinal Waves

In longitudinal waves, particle displacement is parallel to the direction of wave propagation. Sound waves in air are classic examples.

- Compressions: regions where particles are close together.
- Rarefactions: regions where particles are spread apart.

Wave Behavior and Interactions

Reflection

When a wave encounters a boundary and bounces back into the original medium, it is called reflection. The law of reflection states that the angle of incidence equals the angle of reflection.

Refraction

The bending of waves as they pass from one medium to another, caused by a change in wave speed. Snell's Law describes this phenomenon:

$$n_1 \sin \theta_1 = n_2 \sin \theta_2$$

where n_1 and n_2 are the indices of refraction of the media, and θ_1 and θ_2 are the angles to the normal.

Diffraction

The spreading of waves when they encounter an obstacle or slit, more pronounced with larger wavelengths.

Interference

When two or more waves overlap, they interfere. There are two main types:

- **Constructive interference:** When waves are in phase, resulting in increased amplitude.
- **Destructive interference:** When waves are out of phase, leading to decreased or canceled amplitude.

Wave Phenomena and Applications

Standing Waves

Formed when incident and reflected waves interfere constructively and destructively in a medium, creating nodes (points of no displacement) and antinodes (points of maximum displacement). Common in musical instruments and bridges.

Resonance

Occurs when a system is driven at its natural frequency, resulting in large amplitude oscillations. Examples include musical instruments and architectural vibrations.

Sound Waves and Hearing

Sound waves are longitudinal mechanical waves that our ears detect. The pitch of sound is related to frequency, while loudness corresponds to amplitude.

Sample Problems with Answer Keys

Problem 1: Calculating Wave Speed

A wave on a string has a wavelength of 2 meters and a frequency of 5 Hz. What is the wave speed?

Solution:

- Identify known values: $\lambda = 2 \text{ m}$, $f = 5 \text{ Hz}$
- Use the wave equation: $v = \lambda f$
- Calculate: $v = 2 \text{ m} \times 5 \text{ Hz} = 10 \text{ m/s}$

Answer: The wave speed is 10 meters per second.

Problem 2: Understanding Reflection and Angle

A wave strikes a boundary at an incident angle of 30° . If the boundary reflects the wave, what is the angle of reflection?

Answer:

According to the law of reflection, the angle of reflection equals the angle of incidence. Therefore, the angle of reflection is 30° .

Problem 3: Determining Wavelength from Speed and Frequency

A sound wave travels through air at 340 m/s with a frequency of 170 Hz. Find its wavelength.

Solution:

- Use $v = \lambda f$ to solve for λ : $\lambda = v / f$
- Calculate: $\lambda = 340 \text{ m/s} / 170 \text{ Hz} = 2 \text{ m}$

Answer: The wavelength is 2 meters.

Problem 4: Standing Wave Nodes

In a string fixed at both ends, a standing wave has 3 nodes between the endpoints. How many antinodes are present?

Answer:

- Number of nodes: 3 (including endpoints)
- Number of antinodes: Number of segments between nodes = 2

Therefore, there are 2 antinodes in the standing wave.

Question What are the main types of waves covered in a physics classroom wave basics lesson? The main types of waves discussed are mechanical waves (such as sound waves and waves on a string) and electromagnetic waves (such as light and radio waves). How is wave frequency defined and what is its significance in wave behavior? Wave frequency is the number of wave cycles that pass a point per second, measured in Hertz (Hz). It determines the energy and color of electromagnetic waves and influences the pitch of sound waves. What is the difference between transverse and longitudinal waves? Transverse waves oscillate perpendicular to the direction of wave propagation (e.g., waves on a string), while longitudinal waves oscillate parallel to the direction of travel (e.g., sound waves). How does wave speed relate to wavelength and frequency? Wave speed is equal to the product of wavelength and frequency ($v = \lambda \times f$). This means that if the frequency increases and the wavelength remains constant, the wave speed increases accordingly. Sample Problem and Solution

Problem:

A certain electromagnetic wave has a wavelength of 600 nanometers. What is its frequency? Which

part of the spectrum does it belong to, and what are its common uses?

Solution:

- Given: Wavelength (λ) = 600 nm = 600×10^{-9} meters
- Speed of light (c): 3.00×10^8 m/s
- Calculate frequency (f):

$$f = \frac{c}{\lambda} = \frac{3.00 \times 10^8}{600 \times 10^{-9}}$$

$$f = \frac{3.00 \times 10^8}{6.00 \times 10^{-7}}$$

$$f = 5.00 \times 10^{14} \text{ Hz}$$

- Spectrum region: Since the wavelength falls within 400–700 nm, it is within the visible light region.

- Uses: This wavelength corresponds to red light, used in visual displays, lighting, and optical communications.
